

1 Q. Please state your name, by whom you are
2 employed and business address.

3 A. My name is Thomas J. Lord. I am employed by
4 Teknecon Energy Risk Advisors, LLC (TERA). My business
5 address is 1515 South Capital of Texas Highway, Austin,
6 Texas 78746.

7 Q. What position do you hold with TERA?

8 A. I hold the position of Partner.

9 Q. Please describe your experience relevant to
10 this testimony?

11 A. I have been involved, as a both consultant
12 and employee, in the development and deployment of
13 energy risk management systems. This experience
14 includes direct responsibility for assessing,
15 transacting, and managing speculative energy positions
16 utilizing both physical and financial transactions. It
17 also includes guidance for the creation of "best
18 practice" risk policies, procedures and processes for
19 investor-owned utilities and major consumers of
20 electricity. An additional description of my industry
21 experience and educational qualifications is attached.

22 Q. What is the purpose of your testimony?

23 A. The purpose of my testimony is to discuss the
24 requisite internal skills necessary for Idaho Power
25 Company (IPC) to assure price risk management

1 capabilities for its customers, potential mitigation of
2 speculative risks for Idaho Power affiliates due to
3 contractual relationships with Idaho Power, and
4 recommended actions to assure Idaho Power receives
5 appropriate value and rewards from its affiliate
6 relationships whenever Idaho Power receives
7 transactional assistance or provides internal demand
8 and supply information.

9 Q. Please summarize the scope of your testimony.

10 A. I will testify as to my understanding of
11 Idaho Power's ability to manage forward hedging of
12 wholesale energy price risks. I will also testify as
13 to my understanding of certain past practices and
14 transactional patterns that have created or may have
15 created value for Idaho Power affiliates without
16 appropriate compensation to the regulated customers.
17 Finally, I will recommend changes that Idaho Power
18 should adopt to both contractual relationships with
19 affiliates and internal practices that will improve
20 business processes and risk/reward allocation between
21 Idaho Power and its affiliates.

22 Q. IPC testimony (Gale prefiled direct testimony
23 Case No. IPC-E-01-16, pg 4, line 12) indicates that
24 long-term (time periods beyond 30 days in the future)
25 hedging activities may not be performed by IPC in the

1 future. In your opinion, is hedging an appropriate
2 activity for a regulated utility to pursue on behalf of
3 its customers to prudently manage the supply of energy
4 to its customers?

5 A. Regulated utility customers implicitly depend
6 upon the utility provider to make decisions to manage
7 the cost of energy for their consumption. Wholesale
8 energy market price fluctuations, due to internal supply
9 excesses or shortfalls, make the risk of price changes
10 for energy purchases or sales on behalf of the customers
11 significant to individual customers. While hedging
12 decisions are dependent upon a variety of
13 considerations, the failure to make those decisions
14 implicitly exposes the utility consumer to the
15 equivalent of unmanaged speculation.

16 My opinion, therefore, is that a utility must
17 possess the capabilities to determine whether the risk
18 exposure of its customers to future price movements is,
19 in the utility's best opinion, acceptable. The
20 complete reliance upon spot pricing for open market
21 transactions is, implicitly, a speculative decision to
22 accept complete exposure to wholesale market price
23 volatility. Only when a regulated utility has
24 responsibly implemented the internal systems necessary
25 to make and execute hedging, or price risk management

1 determinations on behalf of its customers, can it
2 remove this implicit speculative risk.

3 Q. Why isn't the power cost adjustment an
4 effective hedge against price movement?

5 A. A power cost adjustment ("PCA") mechanism
6 only acts to moderate the rate of change of customer
7 prices by averaging price movements from one year and
8 applying them to the next year's customer rates. It
9 does not, however, remove the risk of adverse price
10 movements. Over time the PCA guarantees the customer
11 will pay average cost of the market prices. The PCA
12 does not remove customer exposure to systemic adverse
13 price movements that are created by the variable nature
14 of customer energy consumption patterns. Therefore,
15 the PCA is not an effective hedging mechanism.

16 Q. What is an effective method of reducing
17 customer exposure to price movements?

18 A. The only method of reducing customer exposure
19 to wholesale price movements is to secure a source of
20 energy which possesses, in some manner, an element of
21 certainty concerning the price of the energy at time of
22 delivery. In contrast, purchasing at "market price" at
23 the time of delivery assures that the energy consumer
24 will be a price taker at the time of purchase. In any
25 wholesale market, a price taker is fully exposed to the

1 ability of suppliers to extract value from the
2 production of the good. In electricity, the wholesale
3 market is perceived as inefficient and subject to the
4 ability of suppliers to extract significant economic
5 value for prompt delivery of energy.

6 It is possible that price risk management
7 activities may result in higher consumer energy costs
8 than relying on spot price purchases for all wholesale
9 energy needs. However, the risk of unmoderated price
10 movements and subsequent abrupt changes in annual
11 prices may be unacceptable to many or all customers.

12 Previously, I discussed the implicit
13 speculation accepted by the decision not to implement
14 price risk management decisions. The possibility of
15 resultant higher energy prices is the risk accepted
16 from the reward of a smaller range of potential pricing
17 outcomes that results from hedging activities. It is
18 this reduction in the range of potential outcomes that
19 reduces the risk of the utility consumer.

20 Therefore, I believe that captive customers
21 should be provided some mechanism by which the
22 customers can opt to be protected from wholesale market
23 price volatility. Price risk management, or hedging,
24 is the logical method of providing that mechanism.

25 Historically, regulated utility customers

1 have depended upon their service provider and
2 regulators to insulate them from wholesale energy
3 markets, either by making long-term market purchases or
4 by constructing generation assets. In the evolving
5 deregulated wholesale energy markets, the forward
6 energy prices will be the factor that determines the
7 advisability of the "build versus buy" decision. The
8 ability to analyze forward market prices and make the
9 correct "build versus buy" decision is a fundamental
10 component of the capability to provide price risk
11 management services to regulated utility customers.

12 Q. What types of organizations possess these
13 Price Risk Management skill sets?

14 A. The speculative activities pursued by Idaho
15 Power affiliates revolve around exactly these skill
16 sets. Speculative transactions that are not based on
17 analysis of forward market prices, the underlying
18 fundamental production costs of the marketplace and a
19 perception of market supply/demand balances, are
20 essentially decisions to place bets without
21 justification for returns. I believe IdaCorp to be a
22 fundamentally well managed organization that would not
23 place its corporate well being at risk for unresearched
24 "gambles." Therefore, I believe that IdaCorp possesses
25 these skill sets internally.

1 These skill sets are contained in affiliates
2 of Idaho Power Company. The specific affiliates that I
3 have identified are:

- 4 • IDACORP Energy Solutions, LP ("IES")
- 5 • IdaWest

6 The second component of the skills necessary
7 to provide price risk management services for regulated
8 customers is the ability to calculate exposures to
9 forward market price movements arising from a customer
10 consumption pattern. It is my understanding that the
11 existing computer hardware and software systems and
12 supporting staff skills were transferred from IPC to
13 IES under the IPC-IES services agreement. It is also
14 my understanding that IdaCorp and IES portrayed to
15 Staff and customers at workshops discussing the IPC-IES
16 services agreement that these resources would still be
17 utilized for regulated customer purposes after the
18 transfer. The responses to staff data requests (see
19 Exhibit 107) indicate that IES has implemented a number
20 of "best practice" risk management practices.
21 Therefore, I believe that IdaCorp's subsidiaries,
22 though possibly not within IPC, have created and
23 possesses the skills necessary for this component of
24 price risk management services.

25 The third component of price risk management

1 is the creation of fundamentally sound internal
2 policies, procedures and processes for the price risk
3 management decision, market transaction execution and
4 processing functions. I have been unable, at this
5 time, to determine the complete nature of the IdaCorp
6 policies and procedures and processes. However, I
7 believe that the IPC policies, procedures, and
8 processes that have been provided for my review prior
9 to this testimony, are not sufficient to assure that
10 IPC decisions to accept or reject long-term
11 transactions for price risk management purposes - or
12 for any other purpose - are made in a consistent and
13 controlled manner. The lack of policies, procedures,
14 and processes undermines any assertion by IPC that
15 price risk management is or is not advisable for the
16 regulated customers. An absence of these structures
17 will inherently make price risk management less
18 consistent and systematized, which frequently results
19 in an internal perception that hedging activities are
20 riskier than they may possibly be.

21 Q. What are the implications of the absence of
22 certain "best practice" risk management systems for
23 IPC?

24 A. This lack of structure also calls into
25 question any prior decisions made by IPC because there

1 is no clear basis for their decision-making. The
2 determination of whether a transaction is advisable
3 depends on three factors: 1) the current prices and
4 implied volatility of prices in the forward market; 2)
5 the net exposure of the risk position to price
6 movements; and 3) the risk tolerance of the entity for
7 which the price risk decision is being made. I
8 acknowledge that there is a wide degree of latitude in
9 what may comprise an acceptable decision based on these
10 factors. I recommend that the Commission grant IdaCorp
11 and IPC a significant amount of future discretion
12 concerning the creation of mechanisms for supporting
13 the price risk management decision.

14 Q. What structure do you recommend Idaho Power
15 create to establish a clear basis for future decision-
16 making?

17 A. I recommend that IPC be obligated to create
18 adequate policies, procedures and process documents to
19 show a well-grounded understanding of these price risk
20 management factors. The ability to evaluate
21 alternatives based on these policies and the capability
22 to make well documented and consistent price risk
23 management decisions are critical to facilitating
24 appropriate regulatory prudence review of the Idaho
25 Power's wholesale energy purchases and sales. Failure

1 to adequately implement policies, procedures, and
2 documentation for risk management decisions will result
3 in continued questions regarding the Company's ability
4 to represent the best interest of its customers. The
5 alternative could be the creation of alternative
6 regulatory or market structures necessary to allow IPC
7 customers the ability to make their own price risk
8 management decisions. If such alternative structures
9 were to be implemented, tariffs would need to be
10 restructured in such a manner as to allow customers to
11 make such decisions external to IPC purchasing
12 practices while retaining the ability to rely upon IPC
13 for the firm supply of energy at market prices. This
14 could include implementing a service structure where
15 customers could receive purely spot market priced
16 energy on a load shaped time of use basis, thereby
17 allowing the customer to access alternate suppliers for
18 risk management products.

19 The documentation that I would expect IPC to
20 implement in this regard are:

- 21 • A clearly stated risk management policy
22 stating the IPC broad objectives for
23 energy risk management (such as reduction
24 in potential volatility of energy
25 prices).

- The delegations of authority and responsibility within the IPC corporate structure to develop and implement risk management structures.
- A clearly stated method for determining the risk tolerance of IPC on behalf of its customers, and the metrics to be used in communicating that tolerance throughout the risk management and senior management organization.
- A clearly stated methodology, including assumptions and recognized areas of uncertainty, for determining the existing exposure to forward wholesale energy market price movements implicit in IPC's consumer sales obligations and generation resources. This methodology should include the ability to reflect exposure to the price risk on an hour-by-hour basis for a determined number of forward delivery months.
- A clearly stated series of procedures and processes for determining and executing hedge strategies and for maintaining and reporting wholesale market transaction

information under that strategy.

1
2 Q. What is your understanding of the
3 relationship between IES and Idaho Power?

4 A. My understanding, prior to the filing of
5 testimony by Idaho Power, was that the Company had
6 transferred its trading and risk management operations
7 to IES under an Electric Supply Management Services
8 Agreement ("Agreement"). In return for that transfer
9 Idaho Power has an obligation to pay IES approximately
10 \$4.8 million per year, which is closely equivalent to
11 100% of the cost of those operations in the most recent
12 rate proceeding for Idaho Power. This transfer between
13 IPC and IES allows IES to participate in the
14 speculative market, and allows the IdaCorp family of
15 companies to retain transactional and risk management
16 skills. Keeping these skill sets within IdaCorp is a
17 benefit to both the Company and the regulated
18 customers.

19 It is my understanding that the retention of
20 skill sets was a critical component of the rationale
21 for approving the Agreement. I believe that the
22 transfer of transactional and risk management skill
23 sets to IES without retaining access to those skill
24 sets significantly diminishes Idaho Power's ability to
25 function effectively in deregulated wholesale energy

1 markets. Since Idaho Power will be compelled to
2 participate in those markets due to the fluctuations in
3 generating capabilities of hydroelectric generation
4 resources, effective participation in the wholesale
5 energy market will be critical to Idaho Power's
6 regulated customers.

7 Q. What is your understanding of the current
8 services provided for Idaho Power by IES?

9 A. In keeping with the understanding expressed
10 above, IES is participating in the near, medium, and
11 long-term markets at the Idaho Power interconnections
12 to the regional markets. Furthermore, IES is gaining
13 insights into the market behavior, expected direction
14 of price movement, and the implied market volatility
15 expected by the trading community. Speculative trading
16 necessitates a significant investment in risk
17 management infrastructure and skills. I believe it was
18 assumed that IES would make these investments to
19 protect its speculative positions, while educating
20 Idaho Power in the process. Because of the \$4.8
21 million dollar cost paid by Idaho Power to IES, it
22 seems rational Idaho Power should receive constant
23 advice and education from IES. My understanding is
24 that Idaho Power would be able to utilize the IES risk
25 management staff to act on behalf of the regulated

1 customers in fashion similar to what they did while
2 Idaho Power had the information and systems necessary
3 to make prudent decisions on behalf of the regulated
4 customers.

5 However, from the testimony of witness Gale
6 in the Commission Case No. IPC-E-01-16 (pg 4 line 12)
7 and Case Nos. IPC-E-7/11 Hoyd (pg 14 line 4), it
8 appears that IES may adopt a more restricted view of
9 these responsibilities under the Agreement. The
10 testimony indicates that the support provided by IES
11 may be restricted to the real time and day-ahead
12 management of the Idaho Power physical deliveries of
13 energy, the "assurance that system resources are
14 managed to the benefit of the customers," and the
15 provision of certain limited audit information.

16 Idaho Power should clearly indicate whether
17 it intends to rely on IES for longer-term price risk
18 management. If my interpretation of the Gale and
19 Andersen testimony is correct, the remaining resources
20 do not appear sufficient for the exercise of prudent
21 actions by Idaho Power within the wholesale power
22 market on behalf of the regulated customers without the
23 skill sets provided by IES.

24 Q. Do you believe that the current interactions
25 between Idaho Power and IES provide instances where the

1 risks and rewards are shifted between IPC and IES are
2 without appropriate customer compensation?

3 A. Yes. IES has received certain benefits from
4 the relationship that have, or could have allowed, IES
5 to transact with lower risk and to shift certain
6 transactional costs to Idaho Power and its customers.

7 The specific areas of concern are:

- 8 • Prior knowledge of market liquidity
- 9 • Credit risks
- 10 • Pricing formulae
- 11 • Regulatory authorities necessary for IES
12 to participate in the wholesale energy
13 market
- 14 • Access to generation optionality

15 Each of these areas will be discussed
16 separately in the following testimony.

17 My fundamental premise is that Idaho Power
18 cannot reduce the risks of IES trading activities
19 without transferring a benefit to IES that is
20 unavailable to other market participants, while at the
21 same time reducing the ability of Idaho Power Company
22 customers to achieve the most competitive market
23 pricing for needed resources. Without transaction
24 specific data, any estimation of whether IES executed
25 transactions to implement some of the benefits, and the

1 degree to which IES was successful in profiting from
2 these benefits, would be highly subjective. However,
3 the fact that such activities could take place without
4 adequate customer compensation, is only an element of
5 the consumer cost. As discussed later, an increased
6 open market transaction costs can arise from market
7 perception of inter-affiliate advantage. Other
8 benefits relating to the reduction of internal
9 transaction or operating costs, such as reduction in
10 credit risks, could be determined from the cost of
11 securing such benefits from the open market.

12 Q. Would it be beneficial for the Idaho Public
13 Utility Commission to create formalized rules for the
14 interaction of IES and Idaho Power?

15 A. No. Any regulatory action that transfers
16 risk and reward between two entities, be it utility and
17 consumer or utility and affiliate, creates a
18 transaction that can be modeled using financial
19 analysis tools. Companies acting in speculative
20 wholesale energy markets should have resources to
21 examine and disassemble financial components to
22 determine the most profitable actions and extract
23 maximum benefit from the regulatory transaction.
24 Frequently, regulatory Staff do not have the training
25 or resources to perform such analysis.

1 Therefore, it can be more efficient and
2 effective in certain instances for regulatory agencies
3 to adopt objective-based criteria that sets forth
4 policies, objectives, and goals. The responsibility
5 for the creation of specific procedures and processes
6 to respond to these objectives is most appropriately
7 left to the Company or group of employees responsible
8 for daily management of the targeted activities. The
9 regulatory agency then reviews the specific procedures
10 and processes to assure their compliance with the
11 objectives. It is frequently more tenable for the
12 regulatory agency to perform the necessary review than
13 to be involved in the micromanagement of financial
14 concepts.

15 I have noted previously certain basic "best
16 practice" risk management structures that should be
17 implemented by IPC. My recommendation is that the
18 Commission develop, preferably in consultation with
19 IPC, the acceptable objective for the IPC risk
20 management policy - reduction of price volatility or
21 the management of prices to a "not to exceed" level,
22 for example - and a complete listing of the types of
23 metrics and reports that are expected to be available
24 to the Commission Staff on an annual basis as the
25 foundation for prudence reviews.

1 I have also recommended that Idaho Power be
2 given the charge to develop price risk management
3 procedures and processes based on basic policies and
4 objectives. That is to allow IPC's discretion in
5 developing these metrics, in coordination with
6 Commission Staff, to best utilize IPC's existing skill
7 sets. This structure is most likely to create the
8 necessary alignment of responsibility and authority to
9 achieve the Commission's goals.

10 Q. What is your understanding of the current
11 pricing for transactions between Idaho Power and IES?

12 A. My understanding is that the pricing of
13 transactions beyond the next delivery day is done at
14 the purchase price. It appears, from Company testimony
15 (IPC-E-01-16, Gale, pg 4- line 15, "all wholesale
16 transaction between Idaho Power and IES will be at
17 market prices" and Gale pg 18 line 2) that no
18 transactions are done directly between Idaho Power and
19 IES for periods beyond next day delivery. IES offers
20 to act as a broker for all such transactions. I have
21 been unable to determine whether IES charges a
22 brokerage fee for arranging such transactions or if
23 such a fee is charged, it is in keeping with normal
24 brokerage fees charged in the industry.

25 For day ahead and real time pricing, IES uses

1 a "representative" market price based on either Mid-C
2 (the Mid-Columbia wholesale market trading hub in
3 Washington state) or Palo Verde (the California-Nevada
4 border wholesale market trading hub) market prices.
5 The pricing is based on the market prices for those
6 points, not the actual transaction costs of IES for
7 securing or selling the power.

8 Any difference between the purchase price and
9 the representative market price, or transmission
10 arbitrage obtained or lost by IES, is retained on the
11 speculative book. Pricing differential and
12 transmission arbitrage opportunities are addressed in
13 subsequent portions of my testimony.

14 Q. What are the trading risks or opportunities
15 that could be experienced by IES in the management of
16 Idaho Power service obligations under the Agreement?

17 A. The manner in which IES interprets the
18 relationship between Idaho Power and IES significantly
19 constrains the risks under the Agreement while
20 retaining a significant number of the advantages.

21 In regards to the short term (real-time and
22 day-ahead), Idaho Power represents the largest market
23 participant for firm energy transactions for power at
24 the interconnections of Idaho Power with other regional
25 market participants. IES, by managing the transaction

1 flow, can assure that Idaho Power and IES are not
2 simultaneously attempting to complete transactions in
3 periods of limited liquidity. In addition, if IES
4 perceives that liquidity at certain pricing locations
5 is constrained, then IES may anticipate that IPC
6 purchases will have the impact of moving wholesale
7 market prices in a specific direction.

8 While this may not impact the pricing at the
9 representative pricing points, it may have a noticeable
10 impact on the Idaho border prices. If IES believes its
11 actions on behalf of Idaho Power could shift the local
12 prices noticeably from the representative prices, IES
13 has the opportunity to create lower risk returns.

14 For example, if IES determines that IPC will
15 require an additional 500 MW per hour of on-peak power
16 three days in the future in a market where the maximum
17 size of on-peak energy trading over the last week was
18 150 MW per hour, then IES may anticipate that prices
19 could move higher. By purchasing block power for
20 future periods in anticipation of this demand, IES may
21 be able to position itself to capture returns due to
22 increased market knowledge. This practice has occurred
23 frequently enough in commodity markets to develop a
24 name "front running" and to necessitate Commodity
25 Futures Trading Commission regulations to prohibit this

1 behavior by commodity brokers.

2 With regard to the long-term markets, IES
3 again has knowledge prior to all other market
4 participants of upcoming Idaho Power market activity.
5 Information given to me indicates that IES is provided
6 and has participated in load forecasting and other
7 activities that define the energy purchasing and sales
8 exposure of Idaho Power. In addition, the audit
9 requests submitted and responded to in this proceeding
10 indicate that IES operates whatever risk position
11 tracking software is utilized by Idaho Power to manage
12 its wholesale market position. I am concerned about
13 the existence, or lack thereof, of software security or
14 firewalls to segregate Idaho Power information from
15 IES.

16 Without these firewalls, IES has access to
17 Idaho Power's intended market activities and
18 consequently has an advantage that no other
19 participants in the Idaho wholesale power market
20 possess - the understanding of when IES's speculative
21 position would be in conflict with future actions that
22 Idaho Power would be expected to assume in the market.

23 For example, a speculator in wholesale power would
24 understand that Idaho Power may at times buy and other
25 times sell. This participant must be concerned that

1 any speculative position would be impacted by Idaho
2 Power activities. If a speculator purchased power for
3 June, only to have Idaho Power soon thereafter
4 determine it had excess power for the upcoming June and
5 therefore need to sell power for that period, the
6 likely result would be that the speculative position
7 would lose money without other market actions.

8 Therefore, knowledge of risk exposure and
9 transaction decisions of Idaho Power prior to other
10 market participants reduces IES's speculative risks in
11 the Idaho region. However, Idaho Power customers
12 receive no benefits from the risk reduction experienced
13 by IES.

14 Q. Do you believe that hedging activity by IPC
15 could reduce the benefit to IES of access to IPC risk
16 positions?

17 A. Yes. Actions by IPC to reduce its wholesale
18 market price risk are, by their nature, intended to
19 reduce IPC's need to transact in the spot market.
20 This reduction should, in aggregate, reduce IPC's
21 competition for short-term market liquidity. Energy
22 commodity markets generally experience their highest
23 volatility, and therefore most rapid price changes, in
24 the delivery month. Prior hedging of risk, by reducing
25

1 IPC's delivery month activities, could reduce IES's
2 knowledge advantage in the marketplace.

3 Q. If Idaho Power Company's purchasing practices
4 changed from entering into transactions for time
5 periods beyond thirty days to a practice of entering
6 into transactions for periods of less than thirty days,
7 do you believe it would create opportunities for IES to
8 benefit from lower risk transactions?

9 A. Yes, I do believe this could create
10 speculative opportunities for IES at lower risk than
11 that of other speculative market participants. As
12 discussed above, knowledge of the activities of
13 organizations with significant market positions allows
14 lower risk trading. Any potential change to increase
15 IPC's exposure to delivery month prices increases IES's
16 knowledge advantage during the period of time when that
17 advantage has the potential to create greatest
18 leverage.

19 Q. How would this occur?

20 A. In this case IES would receive, through its
21 assistance in load forecasting to Idaho Power,
22 knowledge of Idaho Power's need to purchase or sell
23 energy in the wholesale market for forward periods for
24 high, normal, and low water flow scenarios as well as
25 high, normal, and low demand scenarios. With this

1 information, IES has a forecast of the likelihood that
2 Idaho Power will have purchasing or sales transactions
3 during a delivery month. IES can assess the likely
4 market liquidity during that period, estimate the Idaho
5 Power impact on market liquidity during that period,
6 and make appropriate speculative transactions to take
7 advantage of the likely market price direction during
8 that period.

9 This is not to imply that IES, by the nature
10 of this information, is guaranteed profitable trading
11 activities. Abnormal and abrupt conditions can occur,
12 plant outages may take place, and market pressures from
13 interconnected markets -such as California - may
14 overwhelm the market balance of the Idaho region. I am
15 not implying that IES is gaining perfect market
16 knowledge. However, IES is gaining better market
17 knowledge than other participants in the region. This
18 knowledge reduces the risks of speculative activities.

19 It does not appear that the Idaho Power regulated
20 customers have been compensated for that risk reduction
21 in any manner.

22 Without access to all transactions by IES and
23 IPC, information as to whether IES was securing
24 speculative positions to have risk exposures in
25 opposition to IPC, cannot be determined. Without

1 specific transaction level information for both the
2 operational and non-operational books as to what the
3 price movements were from the IES transaction date
4 until the delivery date, I can not estimate the
5 magnitude of IES potential gains from this knowledge.
6 However, it is simple to note that a \$10/MW hr movement
7 for a 100 MW exposure for any given week is \$80,000
8 (\$10/MWH * 100MW * 80 on-peak hours). The price
9 movements experienced during the later portion of the
10 PCA year under review in this proceeding were, at
11 times, orders of magnitude greater. I believe that
12 this is ample evidence that opportunities did exist for
13 IES to make substantial profits from the prior
14 knowledge of Idaho Power purchasing requirements.

15 Q. What additional benefits do you believe
16 IdaCorp and its affiliates received from Idaho Power
17 during last years PCA?

18 A. IES received its FERC power marketing license
19 on April 27, 2001. Prior to that time, IES was not
20 legally authorized to trade wholesale power. IPC
21 responses to staff data request (see Exhibit 107)
22 indicate that all transactions on IES's behalf were
23 actually entered into by Idaho Power. This implies
24 that all counterparty credit risk for IES speculative
25 transactions was actually assumed by Idaho Power. The

1 open market cost of such credit enhancement is normally
2 between 1-2% of the notional amount, i.e., the total
3 value of the transaction as determined by multiplying
4 all volumes for the life of the agreement by the
5 current pricing under the agreement. This is a cost of
6 doing business that IES avoided by receiving free
7 credit enhancement by the regulated customers.

8 In addition, IES was allowed to enter the
9 market months earlier than it could have otherwise,
10 giving IES access to the market volatility of the west
11 during 2000/2001. Prior to receiving its power
12 marketer certificate authority from the Federal Energy
13 Regulatory Commission, it was unlawful for IES to enter
14 into wholesale energy market transactions as a
15 principal. Without Idaho Power standing behind all IES
16 transactions, IES would not have received any profits
17 prior to April 2001. In addition, IES was also allowed
18 to build name recognition in the market place months
19 earlier and will likely be considered part of Idaho
20 Power for several months into the future, extending its
21 credit advantage.

22 Q. Do you believe there are opportunities for
23 IES to obtain minimal or risk-free profits under the
24 IPC-IES pricing methodology?

25 A. Yes, opportunities could exist under the

1 Agreement. In the area of real-time and day-ahead
2 power purchases for Idaho Power by IES, a strong
3 possibility exists for transmission arbitrage under the
4 contract pricing. Arbitrage is an instance where a
5 discrepancy between two different pricing points exists
6 such that a transaction can be entered into to capture
7 the difference as a profit without risk.

8 My understanding is that transmission
9 services are transferred to IES at cost. In addition,
10 power purchased at the Idaho border for Idaho Power by
11 IES is transferred based on the representative market
12 locations - not the border price. Since the
13 transportation price is known, it is possible for IES
14 to determine whether Idaho border prices are less than
15 the representative market price plus transmission. If
16 there is a differential, IES collects that differential
17 as a profit. This profit is risk-free and is not shared
18 with the customers.

19 For example, if for the next day deliveries
20 of energy the Mid-C wholesale energy market is
21 transacting at a value of \$100/MWhr and the price of
22 wholesale energy at the Idaho border with Washington
23 State is \$98/MWhr, an arbitrage opportunity would exist
24 under the pricing formula. As currently utilized, the
25 formula would price energy at the border at a price

1 equal to the Mid-C price plus approximately \$1.25/MWHR
2 of transmission costs - or \$101.25/MWHR. Purchasing
3 energy delivered at the border could occur at a cost of
4 \$98/MWHR without requiring any purchase at Mid-C. The
5 difference between the price under the formula -
6 \$101.25/MWHR - and the market price - \$98/MWHR - would
7 be retained by IES and would have required no risk by
8 IES on the transaction.

9 Another area of potential rewards to IES that
10 is not solely dependant upon the contract pricing
11 mechanism is the creation of speculative positions in
12 anticipation of Idaho Power open market transactions.
13 If IES, through its participation in load forecasting
14 and management of Idaho Power's risk position
15 information, has knowledge that Idaho Power will have
16 the need for significant day-ahead and real-time
17 purchases, IES can enter into speculative transactions
18 that reflect Idaho Power's future needs. For example,
19 if IES has knowledge that Idaho Power will require
20 significant energy purchases for on-peak periods during
21 the next week, IES can take speculative positions to
22 purchase power during that delivery period prior to the
23 execution of the power purchase for Idaho Power. While
24 it is possible that weather or other conditions will
25 remove that need, IES actions will be made with

1 knowledge:

- 2 • of the projected buying or sales needs of
3 the largest firm energy market
4 participant at the interconnections of
5 Idaho Power with other regional market
6 participants,
7 • that IES will know before any other
8 market participant if those needs shift,
9 • that IES will view all market transaction
10 structures of Idaho Power, and
11 • that if IES sells power to Idaho Power at
12 values above the IES purchase price, IES
13 will receive a benefit.

14 Q. Can there be additional costs to Idaho Power
15 customers from the IES relationship?

16 A. Yes. If the other market participants that
17 might transact with Idaho Power perceive that Idaho
18 Power, either explicitly or implicitly, favors IES in
19 its transactions, then there is a significant risk that
20 these market participants may decide to withdraw from
21 the business of providing energy to Idaho Power.

22 Another central premise of deregulated markets is that
23 an open and freely contested market is necessary for
24 efficient market pricing. If the Idaho Power-IES
25 relationship reduces the willingness of third parties

1 to participate actively in the wholesale market for
2 energy at the border of the IPC system, inefficient
3 pricing may occur. This inefficiency may occur during
4 any time period - real-time to multi-year forward
5 periods - that the market lacks an adequate number of
6 participants. These inefficiencies reduce market
7 liquidity and increase prices. Since Idaho Power's
8 regulated customers are paying market prices, they will
9 pay more as a result of decreased liquidity.

10 Several of my recommendations have dealt with
11 the access to internal Idaho Power data by IES prior to
12 other market participants. While the major reason for
13 my recommendations have been to reduce IES's ability to
14 decrease its own risk on speculative transactions in
15 relation to other market participants, the potential
16 reduction in market liquidity and the negative impact
17 on Idaho Power customers if the market loses
18 participants should not be ignored.

19 Q. Are there additional possible benefits that
20 IES may receive from its relationship that current
21 audit information may be unable to identify?

22 A. I believe there are additional risk reducing
23 or risk transferring transactions that would be
24 impossible to identify without access to all trading
25 information for IdaCorp and its affiliates. I am not

1 stating such transactions have or have not occurred,
2 only that information necessary to make a determination
3 is not available at this time.

4 The transaction types referred to above
5 relate to the nature of generation assets as a real
6 option transaction. Generation facilities, in
7 financial engineering terms, constitute a series of
8 options that can be exercised on an hourly, daily,
9 weekly, or monthly basis. Since the generation owner
10 has the right but not the obligation to utilize the
11 generation asset, in financial engineering terms this
12 would be considered owning the option of being "long".

13 The owner of an option has the ability, using
14 financial formulae such as the Black-Scholes option
15 model, to determine the efficient hedge ratio for sales
16 of production against the option to produce output.
17 Financial theory can illustrate that the constant
18 readjustment of this efficient hedging ratio has the
19 effect of allowing risk-free monetization of the
20 production optionality. The only residual risk is that
21 market price movement, or volatility, will not occur
22 and the cost of acquiring the option, the fixed
23 carrying costs of the asset, will not be recovered.
24
25

1 However, in the case of Idaho Power and IES,
2 the fixed carrying costs of the generation assets are
3 recovered through regulated rates. If, and I stress
4 that to my knowledge the information necessary to
5 perform the analysis has not been made available to
6 either myself or IPUC Staff, IES were to transact
7 knowing that Idaho Power generation assets would have
8 excess power to sell in the future, it could be
9 possible for IES to utilize those assets to form the
10 basis for this type of transaction. This type of
11 trading would serve to reduce the risk of IES while
12 providing potentially profitable trading activities.

13 Q. What might be the appropriate relationship
14 between IES and Idaho Power?

15 A. I believe that the definition of appropriate
16 or inappropriate relationships depends upon the
17 alignment of economic interests between Idaho Power and
18 IES. For example, I believe that IES possesses
19 significant market knowledge that would be very
20 beneficial to the regulated customers if they can
21 access it in a nondiscriminatory manner.

22 One way to assure that Idaho Power regulated
23 customers receive that benefit would be for IES and
24 Idaho Power to adopt a corporate policy that, within
25 the acceptable risk tolerance for regulated customers,

1 IES and Idaho Power would always share congruent market
2 views in the region. For example, if IES believes that
3 it is in its best interest to own speculative positions
4 in power for the next June, Idaho Power would assure
5 that it has minimized, to the extent feasible, its
6 exposure to upward price movements for the same period.

7 In this manner, Idaho Power would receive the benefit
8 of IES's market knowledge and counsel on appropriate
9 prudent risk management decisions.

10 In addition, a mechanism for assuring an
11 allocation of transactions entered into during periods
12 of inadequate liquidity could be created. For example,
13 if IPC has requested IES to broker a wholesale
14 transaction to buy energy for a period in which IES is
15 also attempting to purchase energy, an allocation of
16 percentages of requested volumes might be made in
17 instances where total desired volumes cannot be
18 contracted for at the requested prices. In this
19 manner, IPC customers could be assured that IES does
20 not gain an advantage by preferring its own transaction
21 needs over those of the customers.

22 Q. What alternative measure could be required if
23 their practices are not adopted?

24 A. I believe that a failure to adopt "best
25 practice" risk management systems by IPC and a failure

1 to structure the interrelationship between IPC and its
2 affiliates may necessitate Commission action to assure
3 customer protection. As noted previously, those
4 actions could encompass imposition of innovative tariff
5 structures. Other potential actions to assure customer
6 protection could include a complete severance of all
7 transactional and informational ties between IPC and
8 any affiliates, a requirement for transfer of all risk
9 management and execution actions to a third party
10 supplier, or the resumption of forced customer access
11 to the profits obtained by IPC affiliates in the
12 wholesale market. I believe that some or all of these
13 measures may be counterproductive to the long term
14 interests of both Idacorp and its regulated customers.

15 However, a failure to appropriate and effectively
16 manage IPC's price risk and its affiliate relationships
17 would be adequate justification for Commission
18 exploration of alternative measures to protect the
19 regulated customer's interests.

20 Q. Staff has recommended that IES be compensated
21 at the lower of IES's actual cost of purchasing power
22 for consumption or the market price of energy at the
23 "representative price" under the IPC-IES agreement at
24 time of consumption for purchases for Idaho Power
25 regulated customers. Staff has also recommended that

1 Idaho Power be compensated at the higher of IES's
2 actual cost of revenues for sale or the market price of
3 energy at the time of delivery of sales of power by
4 Idaho Power. Do you agree with these recommendations?

5 A. Yes, the IPUC Staff has identified one of the
6 potential flaws in transfer pricing mechanisms - the
7 ability to create risk arbitrage between two locations.

8 Under the current pricing system, IES has the
9 opportunity to determine whether power purchased at the
10 IPC interconnections with other transmission systems is
11 priced at a different value than that represented under
12 the IPC-IES contract price of Mid-C market price plus
13 the tariff costs of transmission to the IPC system from
14 that point.

15 If the cost of wholesale power at the IPC
16 border is less than the IPC-IES reference price for
17 real-time or day-ahead power, the difference is
18 retained by IES. However, IES has taken no risk to
19 obtain that value. Rather, that value is implicit in
20 the IPC customer load and physical assets. Prior to
21 implementation of the pricing structure of this
22 Agreement, risk-free trades were passed on to the
23 ratepayers for their benefit. As such, I agree with
24 Staff that the existing pricing structure under the
25 IPC-IES contract should be modified to assure that the

1 risk-free arbitrage is captured as a customer benefit.

2 I believe that transfer-pricing mechanisms,
3 in general, are a flawed business structure. Because
4 open market prices are dynamic and a transfer-pricing
5 mechanism requires a more static viewpoint, potential
6 arbitrage of the transfer price for one party's benefit
7 will always occur. In organizational structures where
8 inter-departmental cost flows have no overall impact on
9 shareholder value, these inefficiencies may not be
10 fatal. However, in this instance, where inefficiencies
11 may either lead to regulated customer subsidization of
12 non-regulated profits or to non-regulated activities
13 supporting regulated customer costs, the use of
14 transfer pricing becomes problematic.

15 The Staff position recognizes the fundamental
16 concern of transfer pricing between two organizations
17 with differing economic incentives by allocating all
18 risks to one entity and all potential reward to
19 another. While the Staff position clarifies the
20 situation, it is not a sustainable relationship because
21 there would be no economic benefit to IES.

22 I recommend one of two solutions to this
23 problem: either IES must create an internal resource
24 set that trades the Idaho Power real-time and day-ahead
25 obligations without communication with the IES

1 speculative trading activities or Idaho Power should
2 determine whether outsource real-time and day-ahead
3 transaction and risk management could be obtained for
4 less than the \$4.8 million dollar per year cost charged
5 by IES. In the first case the result would be very
6 similar to the relationship in place prior to
7 implementation of the Agreement, with IES maintaining a
8 regulated and non-regulated trading group. In the
9 second case, the information flow would cease to the
10 speculative group.

11 Since Idaho Power audit request response (see
12 Exhibit 107) indicates that no long-term hedging is
13 undertaken by IES on IPC's behalf except at the RMC's
14 direction, either change would only need to impact the
15 real-time and day-ahead trading.

16 In addition, since IES and other affiliates
17 of Idaho Power are speculative market competitors with
18 Idaho Power for market liquidity, I recommend that, in
19 the interest of assuring equitable market rules, the
20 Commission consider ordering:

- 21 1. Any IES Staff in contact with Idaho Power
22 risk management position reports, load
23 forecasting and risk decision analytics
24 be precluded from discussing such
25 information with any person who is

engaged in or who has contact with persons engaged in IES speculative activities; and

2. All Idaho Power risk position, load forecasting and risk decision analytics information be maintained in a secure information system to which IES Staff members can gain access only by specific written permission from Idaho Power Staff ; and
3. No Idaho Power Staff engaged in supporting or making risk management decisions be allowed to hold a position of financial responsibility in IES;
4. Idaho Power must act to obtain market pricing information, market liquidity information and to execute trades for risk management purposes while treating IES as a third-party competitor; and
5. All conversations between Idaho Power risk management Staff and IES Staff must occur on telephone lines possessing recording capabilities and all tapes must be maintained until after the final determination of a Power Cost Adjustment

1 or similar cost recovery proceeding for
2 the period of time pertaining to the
3 conversations has been entered and is no
4 longer subject to appeal; and

- 5 6. No members of the Ida-West or other
6 IdaCorp purely merchant subsidiaries be
7 allowed access to any IPC customer,
8 market forecast, load forecast or risk
9 management information.

10 The first five conditions should be met for
11 as long as the IES-Idaho Power contract is in effect.
12 The sixth condition should be a prerequisite for any
13 IdaCorp merchant activities that are not in whole or
14 part designed to provide services for the IPC regulated
15 customers under Commission regulation.

16 Q. You have recommended that Idaho Power be
17 required to develop price risk management policies,
18 procedures and processes for submission to the
19 Commission. Why is it more appropriate for Idaho Power
20 to develop these procedures than it would be for the
21 Commission?

22 A. TERA has been involved in many engagements
23 devoted to assisting investor owned utilities,
24 municipal utilities and energy consumers in developing
25 price risk management policies, procedures and

1 processes. While there is significant literature
2 describing industry "best practices" in this area, the
3 reality is that no single "off the shelf" control
4 framework is correct for any entity. The best practice
5 for any organization differs depending on internal
6 Staff skills; the ability to implement and utilize
7 complex software systems and the cost versus benefits
8 of said systems for specific applications; the
9 wholesale power market that is being accessed; the
10 liquidity, variety and sophistication of trading
11 products available in that market; and the desire of
12 the organization to utilize personnel or computer
13 resources to provide certain data flow management and
14 security functions. This matrix of varying abilities,
15 needs and resource allocation decisions can not be
16 managed externally, as would be the case if the IPUC
17 imposed price risk management policies, procedures and
18 processes upon Idaho Power. Therefore, I believe that
19 the only organization that can appropriately determine
20 Idaho Power's best practice price risk management
21 policies, procedures and processes is Idaho Power.

22 However, it is possible for an external party
23 to review an organization's policies, procedures and
24 processes to perform a "gap" analysis to assure that
25 adequate safeguards are in place. I do believe that it

1 is appropriate for the Commission to request that the
2 price risk management policies, procedures and
3 processes of Idaho Power be submitted for review and
4 comment. In this manner, the regulated customers are
5 assured that the entity responsible for oversight of
6 Idaho Power actions on their behalf has agreed that
7 Idaho Power has implemented the appropriate controls,
8 allocated adequate resources and will provide the
9 information necessary for legislated regulatory
10 oversight.

11 I believe that Idaho Power should be offered
12 significant latitude and discretion in the drafting and
13 implementation of price risk management systems. The
14 Company is best positioned to know its strengths and
15 weaknesses. Development and review of the price risk
16 management system should be a collaborative, rather
17 than confrontational, process. However, certain
18 fundamental issues need to be addressed to assure that
19 the Idaho Power implementation decisions reflect the
20 understandings reached by Idaho Power, IPUC Staff and
21 Idaho Power customers during the refinement of the
22 Idaho Power - IES contract. These issues include:

- 23 • differentiation of IES and Idaho Power
24 data,
- 25 • protection of Idaho Power customers from

IES arbitrage opportunities,

- consistency of Idaho Power analysis and actions, and
- access of Idaho Power to IES skill sets

My opinion is that, in this manner, the fair and equitable guidelines for prudent price risk management actions by Idaho Power can be achieved. Furthermore, that subsequent PCA discussions can be based upon responses to Idaho Power internal management systems rather than concern over fundamental questions concerning the relationship between Idaho Power and its affiliates.

Q. Does this conclude your testimony?

A. Yes
